Abstract

A bone spreader, comprising two tubular pin holders (7) which are connected to one another by a parallel guide system, and two pins (13) to be connected to the bone parts that are to be spread apart. In order to give the bone parts to be spread apart a more secure position in relation to one another, at least one pin holder (7) is provided with a locking device (12) for a pin (13) located in the pin holder (7). This includes a locking finger (12) which is movable tangentially with respect to the pin holder (7) and which, in the locking position, engages in a transverse groove (14) of the associated pin (13) and can be formed by a pivotably mounted hook.
